# HPLC Separation Modes

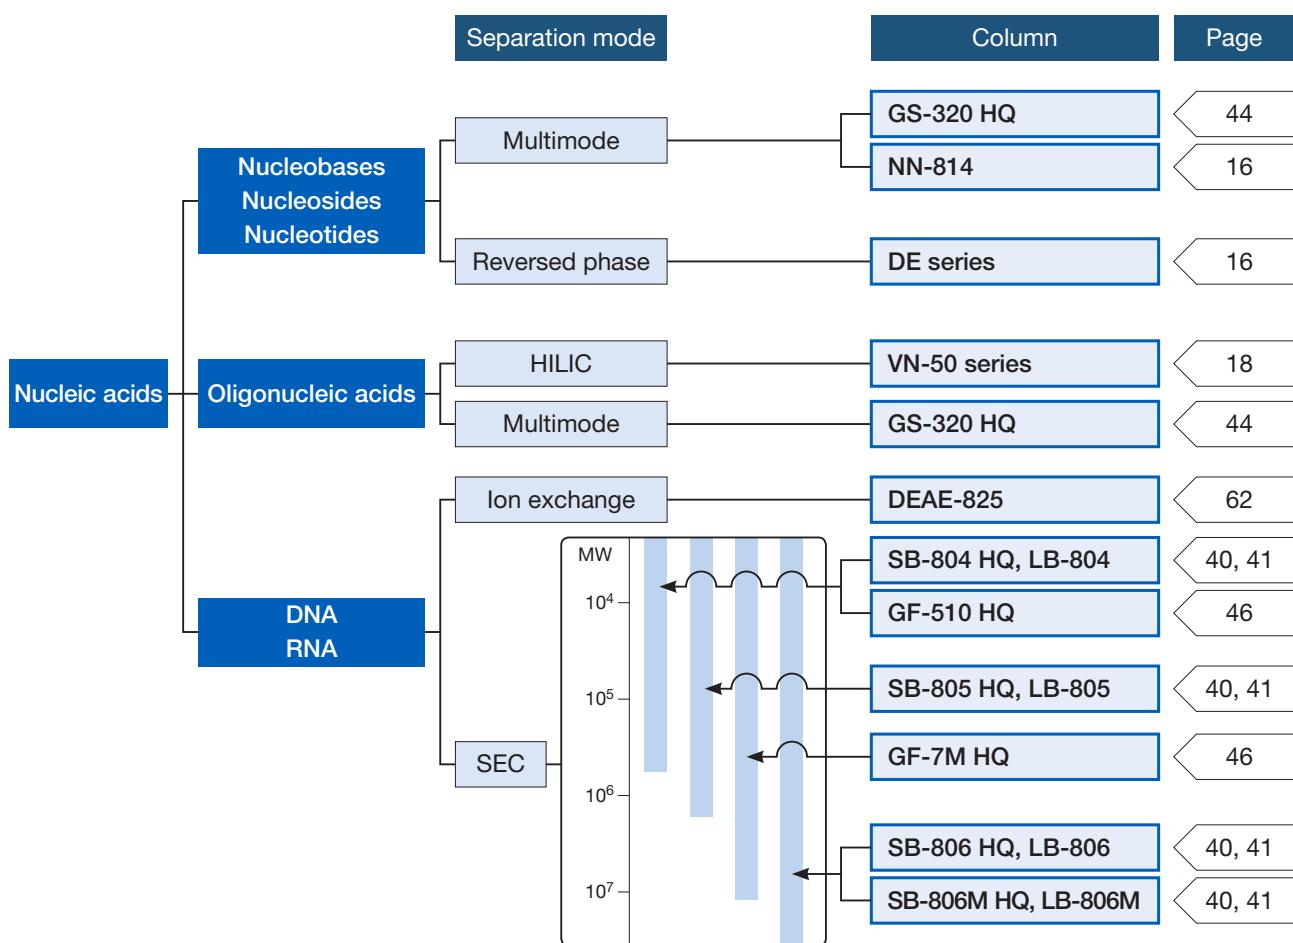

Liquid chromatography (LC) uses liquid as mobile phase (eluent). It is an analytical method that separates a mixture of compounds based on their physical and chemical differences. High performance liquid chromatography (HPLC) is a method that introduces the mobile phase under high-pressure conditions resulting in rapid and high-performance separations. The various interactions between the analyte, stationary phase (packing material), and mobile phase are the key factors for the separation. A wide variety of separation modes can be achieved by using particular combinations of stationary and mobile phases.

Separation mode	Characteristics
Reversed Phase Chromatography (RP)	<ul style="list-style-type: none"> <li>Separation is based on the partition equilibrium between stationary phase and mobile phase.</li> <li>The polarity of the stationary phase is lower than that of the mobile phase.</li> <li>Typically the mobile phase contains a mixture of organic solvents (methanol, acetonitrile, or THF) and aqueous solvents (water or buffer).</li> <li>Use of lower polarity mobile phases fasten the elution.</li> </ul>
Hydrophilic Interaction Chromatography (HILIC)	<ul style="list-style-type: none"> <li>Separation is based on hydrophilic interaction.</li> <li>A high polarity stationary phase is used.</li> <li>Typically the mobile phase contains a mixture of organic solvents such as acetonitrile and aqueous solvents (water or buffer).</li> <li>Using the higher polarity mobile phase causes a faster elution.</li> <li>Applicable for the analysis of high polar substances.</li> </ul>
Ligand Exchange Chromatography (LEX)	<ul style="list-style-type: none"> <li>Separation is based on differences in analytes' coordination complex.</li> <li>Stationary phase modified with metal sulfonate complex ion.</li> <li>Works in combination with size exclusion or HILIC modes.</li> </ul>
Ion Exclusion Chromatography (IEX)	<ul style="list-style-type: none"> <li>Separation is based on electrostatic interaction (repulsion) between the ion exchanger and ionic solutes.</li> <li>Dissociated ionic molecules elute faster than non-dissociated forms.</li> <li>Used mainly for the analysis of organic acids.</li> </ul>
Ion Chromatography (IC)	<ul style="list-style-type: none"> <li>Separation is based on electrostatic interaction (bonding) between the ion exchanger and ionic solutes.</li> <li>Electrical conductivity detector can be used with a mobile phase with low-salt concentration.</li> <li>Used mainly for the analysis of inorganic compounds.</li> </ul>
Size Exclusion Chromatography (SEC)	<ul style="list-style-type: none"> <li>Network or pores on the surface of the packing material works as molecular sieve to separate molecules based on their sizes.</li> <li>To separate molecules solely based on their sizes, it requires an analytical condition without any compounds and packing gel interaction.</li> <li>The bigger the molecule size, the faster the elution sequence.</li> <li>Used for molecular weight or molecular distribution determination of macromolecules and qualification of oligomers.</li> </ul>
Ion Exchange Chromatography (IEC)	<ul style="list-style-type: none"> <li>Separation is based on electrostatic interactions between the ion exchanger and ionic solutes.</li> <li>The mobile phase of choice should have a sufficient buffering capacity at the pH that produces the largest charge differences between the analyte of interest.</li> <li>The elution position is optimized by varying the pH, salt concentration, and/or ionic strength of the mobile phase.</li> </ul>
Chiral Separation Chromatography (CS)	<ul style="list-style-type: none"> <li>Separation of optical isomers using chiral selectors.</li> <li>Highly selective.</li> </ul>
Multimode Chromatography	<ul style="list-style-type: none"> <li>Separation is based on the combination of different modes.</li> </ul>

# Precautions for Polar Polymer Analysis

Unexpected interactions in the column can affect the size exclusion chromatography analysis of polar polymers. These interactions may change elution patterns and results in an invalid molecular weight calculation. It is important to reduce these interfering interactions in order to obtain the accurate molecular weight distribution.

## ~ Interfering interactions likely to be observed ~

### Interactions between the analyte and the packing materials

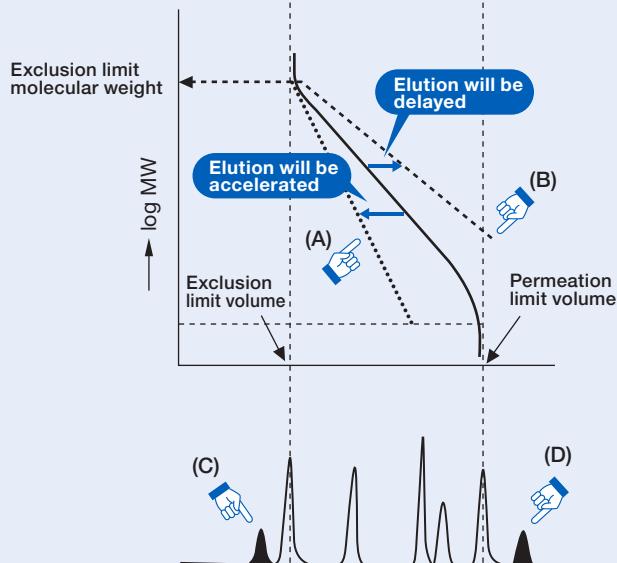

- ◆ Hydrophobic interaction
  - The analyte is adsorbed on the packing material. This delays the analyte elution and results in under estimating the analyte's molecular weight. See (B) and (D).
- ◆ Ionic interaction
  - (1) Ion Exclusion
    - The analyte is repelled from the packing material. This accelerates the analyte elution and results in over estimating the analyte's molecular weight. See (A) and (C).
  - (2) Ion Exchange
    - The analyte is adsorbed onto the packing material. This delays the analyte elution and results in under estimating the analyte's molecular weight. See (B) and (D).

### Interaction within and between the analyte

- ◆ Ionic repulsion effects observed within the multivalent macromolecules causes structure expansion
  - This accelerates the analyte elution and results in over estimating the analyte's molecular weight. See (A).
- ◆ Association between the molecules
  - This accelerates the analyte elution and results in over estimating the analyte's molecular weight. See (A).

### Interactions between the analyte and the solvent

- ◆ The multivalent ion in the solvent works as a bridge to bind ionic molecules (analyte).

## Methods to reduce interactions

### Aqueous SEC (GFC)

#### Ionic interaction

- ◆ Add salt into the eluent

#### Hydrophobic interaction

- ◆ Increase the analyte dissociation
  - Cationic polymer → Lower the eluent pH
  - Anionic polymer → Higher the eluent pH
- ◆ Lower the eluent polarity
  - e.g. Add acetonitrile or methanol

### Organic SEC (GPC)

#### Ionic interaction

- ◆ Add salt into the eluent
  - e.g. Add LiBr to DMF
  - Add  $\text{CF}_3\text{COONa}$  to HFIP

#### Hydrophobic interaction

- ◆ Lower the eluent polarity
  - e.g. Change the eluent from DMF to THF

#### Hydrophilic interaction

- ◆ Increase the eluent polarity
  - e.g. Change the eluent from THF to DMF

### Influence of repeated protein injection on column pressure

ODP2 HP columns are packed with gels with increased surface polarity and smaller pore size which prevent the adsorption of proteins.  
BSA was injected multiple times to both ODS and ODP2 HP columns.  
A significant column pressure increase was observed for the ODS column, while no considerable change was observed for the ODP2 HP column even after 140 injections.

### Comparison of barbital recovery rate using ODP2 HP-2B and ODS in the presence of BSA

LC/MS analysis of drugs in biological samples is often interfered by ion suppression caused by presence of protein when using general ODS columns. However, ODP2 HP does not retain proteins and elutes them at the void volume. Thus, elution of barbital is not affected when using the ODP2 HP and provides better recovery rate than that of an ODS column.

### Alkaline tolerance of ODP-50

**Column :** Shodex Asahipak ODP-50 4D  
**Eluent :** 10 mM NaOH aq. (pH12.0)/CH<sub>3</sub>CN = 35/65  
**Flow rate :** 0.6 mL/min  
**Detector :** UV (254 nm)

### Local anesthetics

Dissociation of tertiary amino groups in basic drugs can be suppressed by making pH of the eluent higher than pKa of the amino groups. This increases the relative hydrophobicity of the basic drugs, thereby allowing the column to retain the drugs stronger and provide baseline separation of them.

### Saccharides anomer separation

Saccharides may present their anomers at lower temperatures. By setting the SUGAR series columns at higher temperatures will prevent the anomer separation and this results in providing better chromatograms of each saccharide.

## &lt;Features of NI-424&gt;

- (1) Enables the separation of  $\text{H}_2\text{PO}_4^-$  and  $\text{F}^-$  which were difficult to separate with I-524A.
- (2) Provides sharper peaks, and resolution between all peaks are well defined. Especially, the separation of  $\text{Cl}^-$  and  $\text{NO}_2^-$  is improved.

### Comparison of LW-803, conventional column, and other manufacturer's column

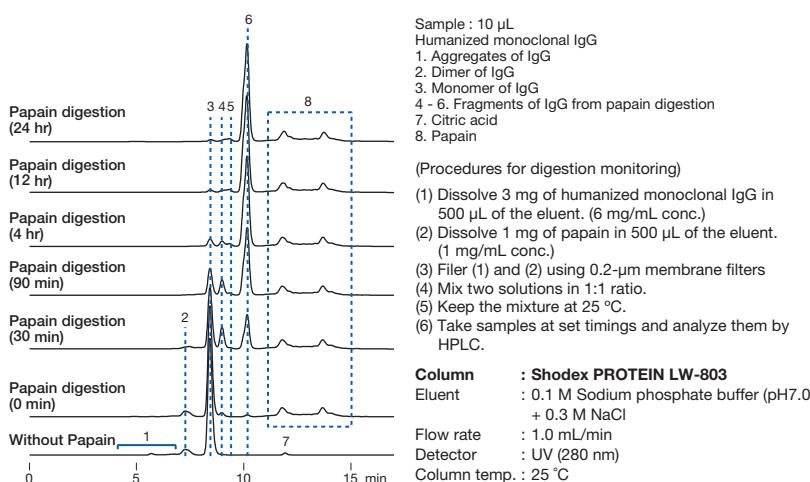

PROTEIN LW-803 is suitable for analyzing a few-hundred-thousand molecular weight size proteins. When comparing LW-803 to our conventional columns and other manufacturer's columns, LW-803 provides a better separation around 160,000 molecular weight range that is about the size of Globulin. This improved separation efficiency is advantageous for the separation of monomer and dimer of IgG which is a mainstream of antibody drug.

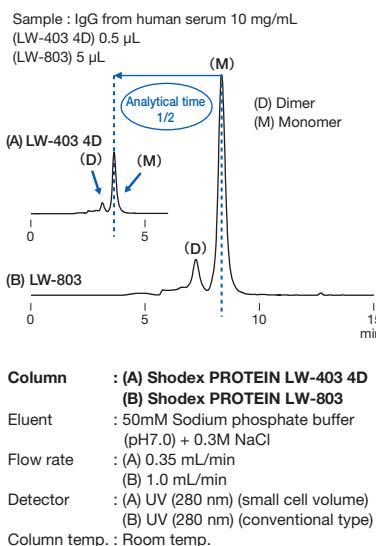

Column : Shodex PROTEIN LW-803, Shodex PROTEIN KW-803, Silica-based SEC column from other manufacturer  
Eluent : 50 mM Sodium phosphate buffer (pH7.0) + 0.3 M NaCl  
Flow rate : 1.0 mL/min  
Detector : UV (280 nm)  
Column temp. : Room temp.

### Monitoring papain digestion of humanized monoclonal IgG

Papain digestion of humanized monoclonal IgG was monitored using PROTEIN LW-803, an aqueous SEC (GFC) column. During the papain digestion of IgG, Fc and Fab fragments from the IgG and their decomposition intermediates are expected to be observed. LW-803 separates IgG and decomposed fragments and intermediates well from each other, thus it is suitable for the monitoring of papain digestion of IgG.

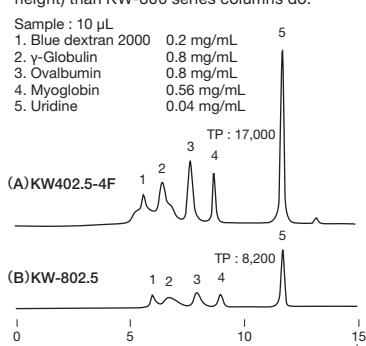

### Efficiencies of LW-403 4D over LW-803 for IgG separation

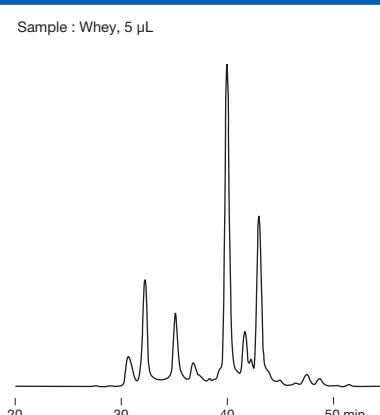

### Comparison of KW402.5-4F and KW-802.5

Effects of sodium nitrate in eluent on the analysis of polyallylamine

For the analysis of cationic polymers, such as polyallylamine, the polymer is observed to adsorb on the column or delayed in elution when low sodium nitrate eluent was used. These phenomena can be suppressed by increasing the concentration of sodium nitrate in the eluent. In the case of polyallylamine, a good shape chromatogram is obtained when sodium nitrate concentration is 0.1 M or higher.

### Peptides

GS-HQ columns work not only under SEC (GFC) mode, but also under multimode, adding hydrophobic and ionic interactions. By carefully selecting the eluent, they provide separation mode that was not available with other types of columns. GS-320 HQ shows excellent performance separating hydrophilic peptides, particularly for acidic and basic peptides.

### Purine bases in beer

Purine in food is analyzed as purine base after steps of sample preparation; homogenization, freeze drying, hydrolyzation with 70 % perchloric acid, and neutralization. Example below shows the analysis of purine in regular beer and beer treated with guanase (an enzyme that degrades guanine to xanthine). The following data indicate that guanine was decreased and xanthine was increased by guanase.

### Low molecular weight water-soluble dietary fiber

GS-220 HQ allows to elute monosaccharides, disaccharides, and sugar alcohols after the indigestible component fraction (indicated by an arrow on the chromatogram). This separation makes the method preferable for the quantification of low molecular weight water-soluble dietary fiber.

## Comparison of two GF column performances for the separation of maltooligosaccharides

GF-210 HQ demonstrates an improved separation of low molecular substances. The chromatograms below show that the peaks obtained by GF-210 HQ are separated with deeper notches compared to peaks obtained by GF-310 HQ. GF-210 HQ is capable of separating oligosaccharides (trisaccharides to hexasaccharides) while those oligosaccharides were eluted all together when analyzed by GF-310 HQ.

**Comparison of HK-404L and conventional column (KF-805L)**

**HK-404L**

HK-404L keeps low column pressure even at high flow rates using a conventional HPLC instrument. This allows it to achieve ultra-rapid analysis; reducing its analysis time to about 1/6 of conventional analysis method's analysis time. Also, its elution volume per column is about 2.0 mL which is about 1/6 of the conventional column's elution volume.

# Column Cleaning

Problems in peak shapes and elution timing changes or elevated column pressure etc. are often caused by insoluble or adsorbing components present in the eluent and reagents being deposited inside the column. These problems may be resolved by cleaning the column.

This section describes general signs of column deterioration and column cleaning procedures.

Please also read column-specific detailed cleaning procedures included in the product operation manual.

## ■ Typical signs of column deterioration

1. Elevated column pressure
2. Abnormal peak shapes (broadening, leading, tailing, and split peaks)
3. Change in retention time
4. Unstable baseline

## ■ Standard cleaning procedures

### 1. Insoluble components

Insoluble components that block the column inlet may be removed by reversing the flow direction, i.e., introducing the eluent from the column outlet, with flow rate at less than half of the recommended flow rate.

### 2. Adsorbing components

For an efficient cleaning, reverse the flow direction and reduce the flow rate at half of the recommended flow rate.

## ■ Cleaning solvent selection guide

Solvents capable of dissolving the adsorbed substances

Solvents with high eluting power (depends on separation mode)

**\*use only the solvents allowed in the operation manual**

## Methods

Reversed phase chromatography columns	<p>Use a solvent with higher organic solvent concentration such as methanol, acetonitrile, or THF. (When using a mixture of buffer solution and organic solvent, make sure there is no precipitation of salt.)</p>
Sugar analysis columns	<p><b>[Ligand exchange columns (SUGAR series) ]</b> To regenerate the detached counter ions. - Flush or inject aqueous salt solvent which contains the modified counter ion. <b>[Polymer-based amino columns (NH2P series and VG-50 series) ]</b> Adsorption of acidic substances on the amino functional group. - Flush with solvents in the following sequence; water, 0.1 M NaOH (aq.), water, and the eluent.</p>
Aqueous SEC (GFC) chromatography columns	<p>Adsorption of ionic substances. - Use a solvent with higher salt concentration or solvent with different pH from the eluent. Adsorption of hydrophobic substances. - Use a solvent containing organic solvent. (When using a mixture of buffer solution and organic solvent, make sure there is no precipitation of salt.)</p>
Ion exchange chromatography columns	<p>Adsorption of ionic substances. - Use a solvent with higher salt concentration or solvent with different pH from the eluent. Adsorption of hydrophobic substances. - Use a solvent containing organic solvent. (When using a mixture of buffer solution and organic solvent, make sure there is no precipitation of salt.)</p> <p>Adsorption of protein. - Inject 1 - 2 mL of 0.1 M NaOH (aq.) or 30 % acetic acid (aq.) several times.</p>

\*Recommended solvent volume to introduce is 5 to 10 times the column volume.

\*Pay attention to the column pressure elevation during column cleaning.

\*Column cleaning is limited and does not guarantee full recovery of the column to its original condition.

# General Precautions for Column Handling

For the best performance of the column, please follow the instructions given below.

## ■ HPLC System Preparation

- Wash entire LC system prior to the column installation, including all flow-lines and sample loop by switching the valve, and then replace the washing solution with the eluent to be used.
- If desired new eluent has low miscibility/solubility to the eluent of previous analysis, first use the eluent that is miscible/soluble to both eluents, and then replace it with the desired eluent.
- \*If the eluent left in the system is not compatible with the column to be used, it may damage the column.
- \*A drastic change in the eluent compositions may remove substances adsorbed on the system and they may enter and deteriorate the column.

## ■ Column Installation

- Connect the column to LC system by following the “flow direction arrow” (➡) indicated on the column name tag. If guard column is used, position the guard column in front (before the inlet) of the analytical column.
- Make sure to insert the tubing all the way to the end fitting and secure it with the male nut. It is important that there is no extra space between the tubing and the column side of the end fitting. Presence of an extra space will let the sample to spread out and may result in wide peaks.
- Set the initial flow rate at less than half of the recommended flow rate and start the system. If using the column at an elevated temperature, keep a low flow rate until the temperature of the column reaches to the set temperature, and then gradually increase the flow rate to the desired.
- \*Verify that there is no solvent leak. It may cause electronic leakage, rust, and/or chemical injury.
- \*Make sure not to let air bubbles enter the column while installing the column. The air bubbles may damage the column.
- \*When restarting the system after column installation or after holding the eluent flow, start the system at less than half of the recommended flow rate. A rapid increase in pressure can damage the column.
- \*If the column was used at an elevated temperature, lower the flow rate to less than half of the recommended flow rate at the end of analysis. Then, turn off the column oven, and let the column temperature return to room temperature before stopping the pump. If the pump was stopped while the eluent inside the column was still hot, as the eluent temperature decreases, its volume also decreases. This may result in creating an empty space in the column and deteriorates the column.
- \*It is recommended to set the pump limiter to avoid exceeding the maximum pressure.

## ■ Solvent Exchange

- When replacing the solvent, start the system at less than half of the recommended flow rate. Recommended solvent volume to introduce at each step is 3 to 5 times of the column volume.
- Check miscibility/solubility of the desired new solvent and the solvent currently filled in the column.
- When replacing the current solvent with a solvent with low miscibility/solubility to the current solvent, first use a solvent that is miscible/soluble to both eluents, and then replace it with the new solvent.
- When using a gradient method, changes in the eluent compositions may increase the column backpressure. Adjust the flow rate and column temperature so that the column backpressure remains below the usable maximum pressure.

## ■ Column Storage

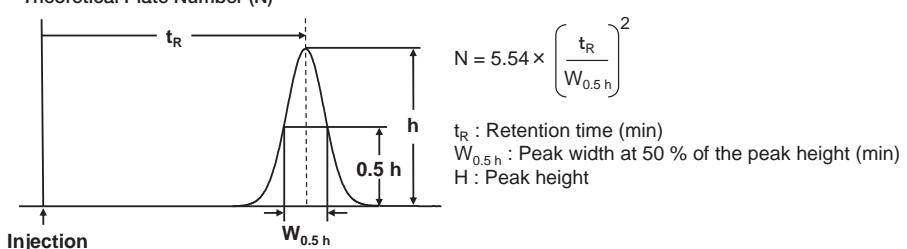

- Remove the column from the system after replacing the in-column solvent with the shipping solvent. Securely tighten the end caps and store the column at a location with stable temperature (a cool and dark space is recommended).
- \*Never allow inside of the column to dry. It can damage the column.

## ■ Column Inspection

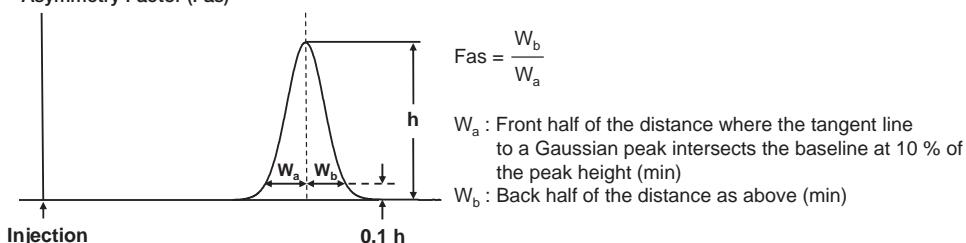

Inspection method is described in the Certificate of Analysis (CoA).

Theoretical Plate Number (N) and Asymmetry Factor (Fas) were calculated using the below equations.

### • Theoretical Plate Number (N)

### • Asymmetry Factor (Fas)

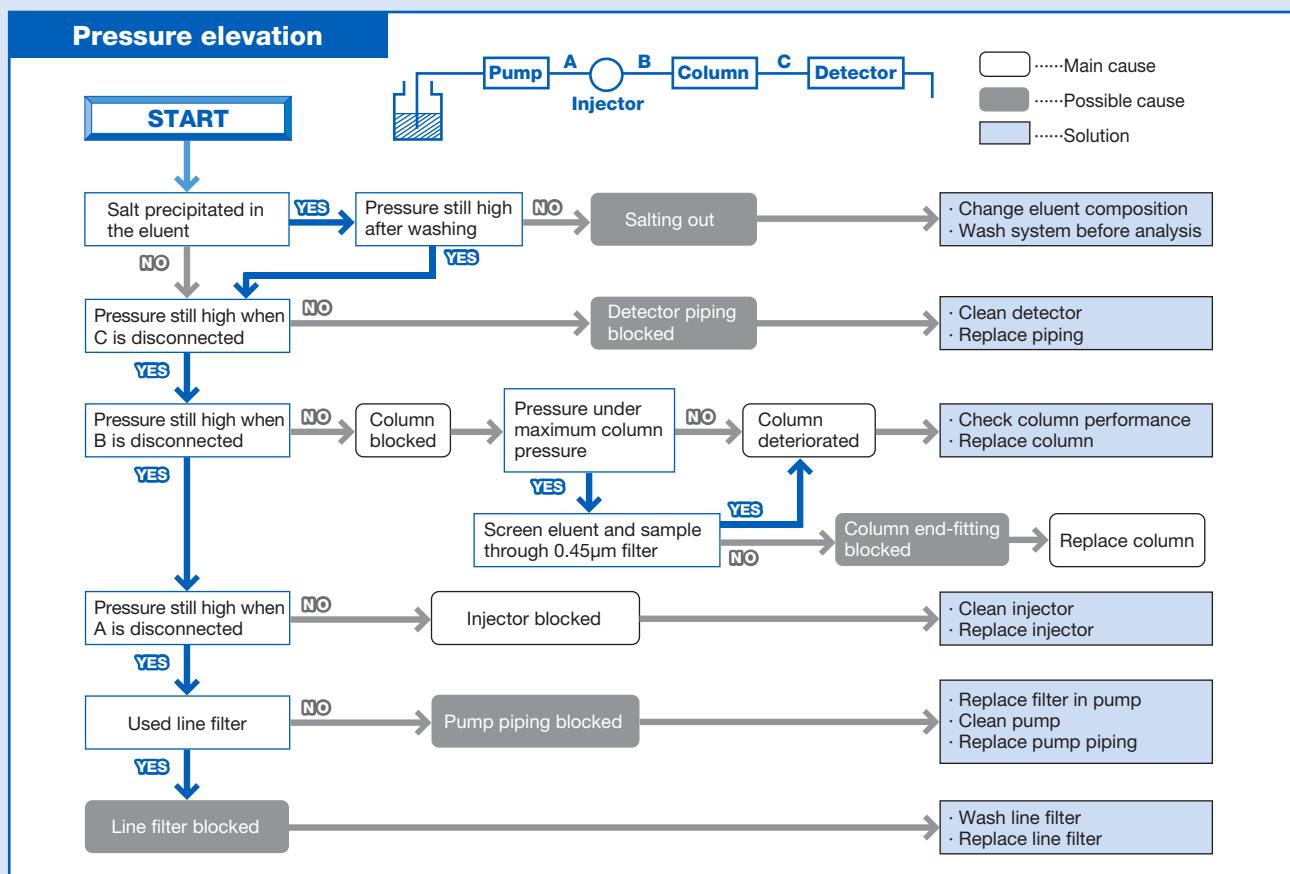

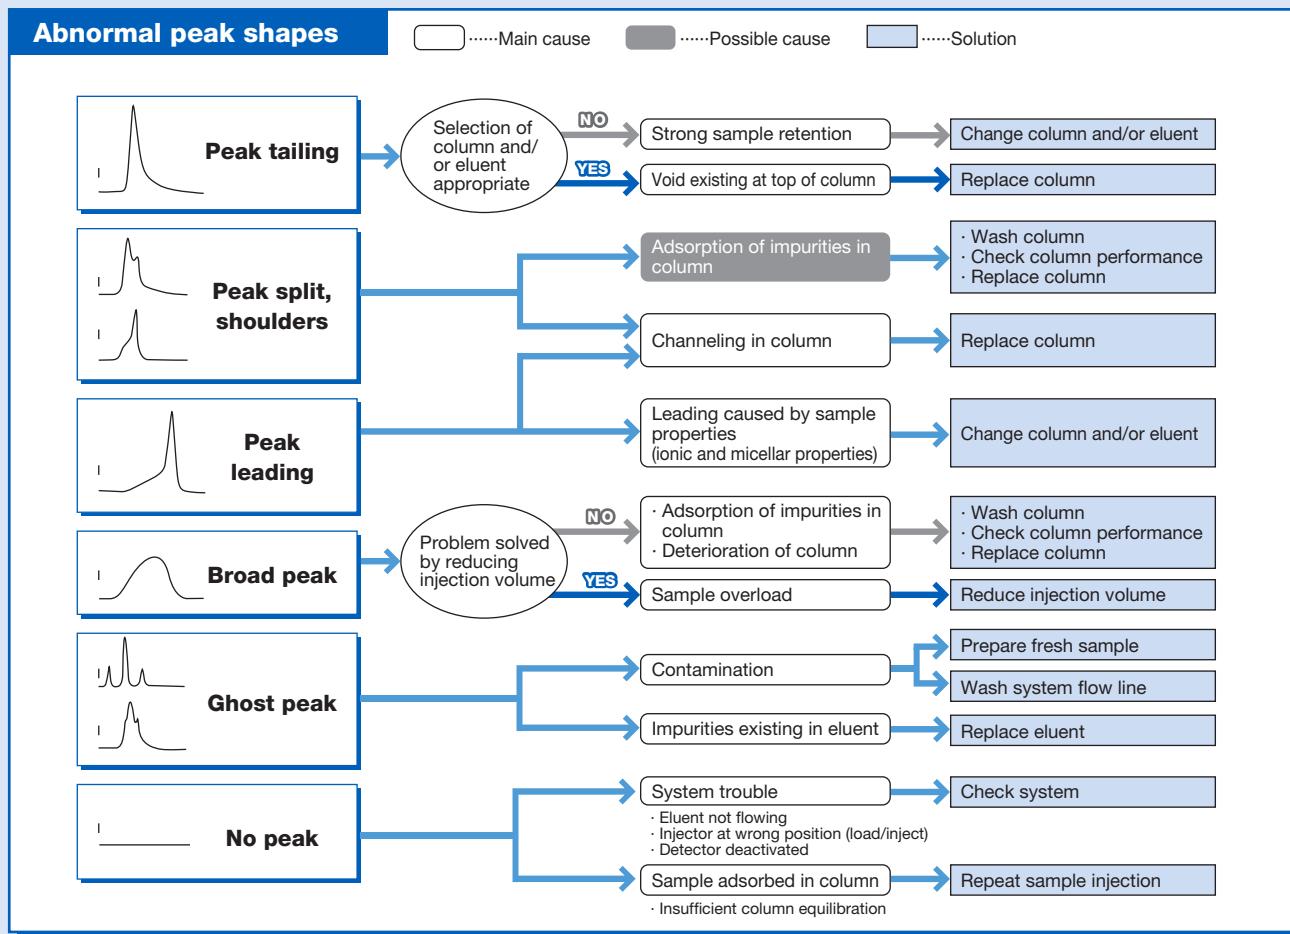

## ■ Additional Warnings

- Do not remove end fittings.
- Do not make a strong impact on the column. Do not drop or hit the column on a hard surface.

\*Read the operation manual before using the column.
